The present research interest in nuclear structure of a borromean system $^9$Be ($\alpha + \alpha + n$) is threefold: 1) nucleosynthesis of $^9$Be by the $^8$Be(n,$\gamma$)$^9$Be reaction via the 1/2$^+$ state near neutron threshold; 2) the nature of the 1/2$^+$ state; and 3) the nature of pygmy dipole resonance. Photodisintegration of $^9$Be was measured from the nucleosynthesis point of view in two experiments with laser-Compton scattering $\gamma$-ray beams [1, 2], which however resulted in a significant discrepancy in peak cross section immediately above the n + $^8$Be threshold. The nature of the 1/2$^+$ state is not elucidated experimentally though it can be a virtual state as discussed in the literature [3-5]. Furthermore, low-energy E1 strengths in $^9$Be referred to as pygmy dipole resonance (PDR) are not well investigated experimentally; the only existing data were obtained with bremsstrahlung [6].

We carried out a new measurement of photodisintegration of $^9$Be through the 1/2$^+$ state and PDR at the NewSUBARU facility. Quasi-monochromatic $\gamma$-ray beams with 1 – 2% energy spreads in FWHM were produced in laser Compton backscattering (LCS) from relativistic electrons in a range of 954 - 1121 MeV. A grating-fixed CO$_2$ laser ($\lambda=10.5915 \mu$m) was used to produce 1661 - 2232 keV (in maximum energy) $\gamma$-ray beams for the study of the 1/2$^+$ state, while a Nd:YVO$_4$ laser ($\lambda=1064$nm) to produce 5.78 – 16.93 MeV $\gamma$-ray beams for PDR. A 99% $^9$Be rod of 20mm in diameter and 40mm in length was irradiated. It is of essential importance to understand the characteristics of the LCS $\gamma$-ray beams used for the present experiment, i.e., the energy distribution, energy calibration, and flux. The characteristics of the $\gamma$-ray beam are presented in a poster separately.

We present photoneutron cross sections for the 1/2$^+$ state with improved accuracy with emphasis on its threshold behavior. It is shown that the peak cross section is rather consistent with the one reported in 2001 [1]. We also present photoneutron cross sections for PDR which follow the cluster dipole sum-rule [7].
